Chapter 1

The Network Protocol

.

1.1 Overview

Loconet is a peer to peer distributed network system on which all devices can monitor the network data flow. The network is event driven by different devices in time, and is not polled by a centralised controller in normal operation. The normal the network state is idle, with no data traffic unless a device has information to send. With no traffic flow, the network is quiet.

The network data is sent in asynchronous format using 1 start bit, 8 data bits and 1 stop bit. The 8 bit data is transmitted least significant bit first. The bit times are 60.0 μ S or 16,660 baud +/- 1.5%. A computer can connect to a Digitrax USB interface at higher baud rates and the device will make the necessary conversion. Bytes may be transmitted back-to-back, with a start bit immediately following the stop bit of the previous character.

Any message that has format or framing errors, data errors or is a fragment caused by noise glitches and does not completely follow the message format will be ignored by all receivers, and a new opcode will be scanned for re-synchronisation.

The OPC_BUSY opcode is included to allow the master to keep the network active whilst it is performing a task that requires a response, and entails a significant processing delay, i.e. it can ensure no new requests are started until it has responded to the last message. This OPC_BUSY opcode should be simply stripped and ignored.

If a device disconnects from the network and so does not access or reference a slot within the

system purge time, the command station will force the un-accessed slot to common status so other system devices can use the slot. The typical purge time of a command station is about 200 seconds. A good "ping" or slot update activity is about every 100 seconds, i.e. if a user makes no change to a throttle/slot within 100 seconds, the throttle/device should automatically send another speed update at the current speed to reset the purge timeout for that slot.

1.2 Message Format

All the network communications are via multi-byte messages. The command station is defined as the device that is maintaining the refresh stack for DCC packet generation and is actively generating the DCC track data. Refresh of information is typically only performed for mobile decoders. Stationary type decoders are not refreshed and individual immediate commands are sent out to the track as requested.

The command station is only privileged in respect to performing the task of maintaining the locomotive refresh stack and generating DCC packets. In this way other network transactions may occur that the command station does not need to be involved with or understand, as long as they follow the message protocol and timing requirements. i.e. other devices may have a dialog on the network without disturbing or involving the command station. Devices on the network monitor the messages, check for format and data integrity and parse good messages to decode if action is required in the context. Devices such as throttles, input sensors, computer interfaces and control panels may generate the network messages without needing prompting or polling by a central controller.

Devices frequently will be added and removed from an operating the network. The devices and protocol are tolerant of electrical and data transients. The format chosen gives a good degree of data integrity, guaranteed quick network-state synchronisation, high data throughput, good distribution of access to many competing devices and low event latency. Also, the devices may be operated without need for unique ID or other requirements that can make network administration awkward.

The data bytes on the Network are defined as 8 bit data with the most significant bit as an opcode flag bit. If the most significant bit, d7, is 1 then the 7 least significant bits are interpreted as a network opcode. The opcode byte may only occur once in a valid message and is the first byte of a message. All the remaining bytes in the message must have a most significant bit of 0, including the last checksum byte. The checksum is the 1's complement of the byte wise exclusive or of all the bytes in the message, except the checksum itself. To validate data accuracy, all the bytes in a correctly formatted message are exclusive or'ed. If this resulting byte value is 0xFF, then the message data is accepted as good.

The opcodes may be examined to determine message length and if subsequent response message is required. Data bits d6 and d5 encode the message length. The message length includes the opcode and the checksum bytes. The bit d3 = 1 implies that a follow-on message or reply is expected.

d7	$\underline{d6}$	$\underline{\mathrm{d}5}$	$\underline{d4}$	$\underline{d3}$	$\underline{d2}$	$\underline{d1}$	$\underline{d0}$	
1	0	0	\mathbf{E}	D	\mathbf{C}	В	A	2 byte message
1	0	1	\mathbf{E}	D	\mathbf{C}	В	A	4 byte message
1	1	0	\mathbf{E}	D	\mathbf{C}	В	A	6 byte message
1	1	1	\mathbf{E}	D	\mathbf{C}	В	A	Variable length message. The
								next byte in the message is a 7
								bit byte count.

The A,B,C,D,E are bits available to encode 32 opcodes per message length.

1.3 Refresh Slots

The command station standard refresh stack is an array of up to 120 read/write refresh slots. The slot address is a principal component and is generally the second byte or 1st argument of a message to the master. The standard refresh slot contains up to 10 data bytes relating to a locomotive and also controls a task in the track DCC refresh stack. Most mobile decoder or locomotive operations process the slot associated with the locomotive to be controlled. The slot number is a similar shorthand ID# to a file handle. Slot addresses 120-127 are reserved for system and command station control. Slot #124 (0x7C) is allocated for read/write access to the programming track, and the format is not the same as a standard slot. The DCS240 command station has 400 read/write refresh slots. The additional slots in excess of the 120 standard slots are accessed by using extended opcodes. The DCS210 also supports the extended opcodes though it only has 100 refresh slots.

1.4 Standard Address Selection

To request a mobile or locomotive decoder task in the refresh stack, a throttle device requests a locomotive address for use (OPC_LOCO_ADR). The command station responds with a slot data read for the slot (OPC_SL_RD_DATA), that contains this locomotive address and all of its state information. If the address is currently not in any slot, the command station will load this new locomotive address into a new slot (speed=0, direction forwards, functions off and 128 step mode) and return this as a OPC_SL_RD_DATA. If

no inactive slots are free to load the new locomotive address, the response will be the OPC_LONG_ACK with a fail code 0x00.

The throttle/computer must then examine the slot data bytes to work out how to process the command station response. If the slot status 1 byte shows the slot to be common idle or new the throttle may change the slot to in use by performing a null move instruction (see OPC_MOVE_SLOTS) on this slot. This activation mechanism is used to guarantee proper slot usage interlocking in a multi-user asynchronous environment.

If the slot return information shows the locomotive requested is in use or up-consisted (i.e. the SL_CONUP, bit 6 of slot status 1=1) the user should not use the slot. Any up-consisted locomotives must be unlinked before usage. Always process the result from the OPC_LINK_SLOTS and OPC_UNLINK_SLOTS commands, since the command station reserves the right to change the reply slot number and can reject the linking tasks under several circumstances. Verify the reply slot number and the link UP/DN bits in slot status 1 are as you expected.

The throttle will then be able to update speed, direction and function information. Whenever slot information is changed in an active slot, the slot is flagged to be updated as the next DCC packet sent to the track. If the slot is part of linked consist slots the whole consist chain is updated consecutively.

If a throttle is disconnected from the the Network, upon reconnection (if the throttle retains the slot state from before disconnection) it will request the full status of the slot it was previously using. If the reported status and speed, function data etc., from the command station exactly matches the remembered slot state the throttle will continue using the slot. If the slot data does not match, the throttle will assume the slot was purged free by the system and will go through the setup log on procedure again.

With this procedure the throttle does not need to have a unique ID number. slot addresses do not imply they contain any particular locomotive address. The system can be mapped such that the slot address matches the locomotive address within, if the user directly reads and writes to slots without using the command station to allocate locomotive addresses.

1.5 Messages

1.5.1 OPC_BRD_OPSW

Operation: Read and write board option switches.

Group: 6-Byte Message

Direction: \rightarrow Command Station

Encoding:

Byte 0:

1	1	0	1	0	0	0	0	0xD0	Opcode.
---	---	---	---	---	---	---	---	------	---------

Byte 1:

0	1	1	d4	0	0	1	d0

indicates read/write direction. 1 means write and 0 means read.

Byte 2:

Byte 3:

1.5.6 GetLocoSlotDataLAdrV1

Description:

This command requests the slot number for the selected locomotive address. If the locomotive is found in the slot table then the command station returns an **LocoSlotDataV1** message with the slot information. If it is not found then the command station will put the locomotive into a free slot and then return an **LocoSlotDataV1** message with the slot information. If there are no free slots then the command station returns an **Acknowledgement** containing the error code.

The command station will generate NMRA 14 bit or long address packets for the locomotive. The address must be in the range 128 to 9983.

Group: 4-Byte Message Opcode: OPC_LOCO_ADR Type: Command Encoding: Byte 0: 1 0 0xBFOpcode. 1 1 1 1 1 1 Byte 1: 0 <ADR2>Address high 7 bits. n n n \mathbf{n} n n n Byte 2: 0 <ADR> Address low 7 bits. \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} Byte 3: 0 <CHK> Checksum. \mathbf{n} n n \mathbf{n} n n n

1.5.14 OPC_LINK_SLOTS

Operation: Link slots. Group: 4-Byte Message Direction: \rightarrow Command Station Encoding: Byte 0: $1 \quad 0$ Opcode. 1 1 0 0 1 0xB9Byte 1: 0 Slot number in the range 0x00 to n n <SL1> n \mathbf{n} n n \mathbf{n} 0x7F.Byte 2: $\langle SL2 \rangle$ Slot number in the range 0x00 to 0 n \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} n 0x7F.Byte 3: 0 <CHK>Checksum. n \mathbf{n} n \mathbf{n} \mathbf{n} \mathbf{n} n

Description:

This function links slot SL1 to slot SL2. The command station sets SL_CONUP/DN flags appropriately. Invalid link will return a fail acknowledgement.

Response:

OPC_SL_RD_DATA or OPC_LONG_ACK.

Notes:

$1.5.15 \quad OPC_LOCO_DIRF$

Operation: Set locomotive direction and function	F0 to F4 states.
Group: 4-Byte Message	
$\underline{\text{Direction:}} \ \to \text{Command Station}$	
Encoding:	
Byte 0:	
$egin{array}{ c c c c c c c c c c c c c c c c c c c$	Opcode.
Byte 1:	
0 n n n n n n n m	Slot number in the range $0x00$ to $0x7F$.
Byte 2:	
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	Locomotive's direction and state of functions F0 to F4.
d6 Reserved. Set to 0. d5 Locomotive direction. 1 means forward, d4 F0 state. 1 means on, and 0 means off. d3 F4 state. 1 means on, and 0 means off. d2 F3 state. 1 means on, and 0 means off. d1 F2 state. 1 means on, and 0 means off. d0 F1 state. 1 means on, and 0 means off. Byte 3:	0 means backwards.
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	Checksum.
Description:	
This function sets the locomotive's direction and	function F0 to F4 states.
Response:	
None.	
Notes:	
None.	

1.5.16 OPC_LOCO_DIRF_EXT

Operation: Set locomotive direction and function F0 to F28 states for extended slots.

Group: 6-Byte Message

 $\underline{\text{Direction:}} \ \to \text{Command Station}$

Encoding:

Byte 0:

1	1	0	1	0	1	0	0	0xD4	Opcode.

Byte 1:

0	0	1	0	0	d2	d1	d0	0x2 < SLOTP >	Bits d2 to d0 contain the extended
									slot page number in the range $0x0$
									to $0x7$.

Byte 2:

$\begin{bmatrix} 0 & n & n & n & n & n & n \end{bmatrix}$ $\begin{bmatrix} n & n & n & n & n \end{bmatrix}$ $\begin{bmatrix} SLOT\#> \end{bmatrix}$ Extended slot num

Byte 3:

0	0	0	0	0	1	0	0	<subc></subc>	Subcode.
---	---	---	---	---	---	---	---	---------------	----------

Byte 4:

0 d6	d5 $d4$	d3 d	2 d1	d0	<dir.< th=""><th>FX></th><th>Direction and function sates.</th></dir.<>	FX>	Direction and function sates.
SUBC	<u>d6</u>	d5	$\underline{d4}$	<u>d3</u>	$\underline{d2}$	<u>d1</u>	<u>d0</u>
0x05	0	0	0	0	F28	F20	F12
0x06	0	DIR	F0	F4	F3	F2	F1
0x07	F11	F10	F9	F8	F7	F6	F5

Description:

This command sends the data from one device to another peer to peer.

$\underline{\operatorname{SRC}}$	$\overline{\mathrm{DSTL}}$	$\overline{\mathrm{DSTH}}$	Comments
0x00			Source is command station.
Don't Care	0x00	0x00	Broadcast Message.
0x70 to $0x7E$			Reserved.
0x7F	0x00	0x00	Broadcast throttle message transfer.
0x7F	ID1	ID2	Throttle message transfer. ID1 and ID2 en-
			code ID.

Response:

None

Notes:

None.

1.5.26 OPC_PEER_XFER_20

Operation: Move bytes peer to peer.

Group: Variable-Byte Message

 $\underline{\text{Direction:}} \ \ \text{device} \to \text{device}$

Encoding:

Byte 0:

		1	1	1	0	0	1	0	1	0xE5	Opcode.
--	--	---	---	---	---	---	---	---	---	------	---------

Byte 1:

Byte 17:

Byte 18:

0 1 2 1 2 1 2 1 2 1 2 1 2 1 2 1 2 1 2 1	0	n	n	n	n	n	n	n	<d8></d8>	Data item 8. Low 7 bit
---	---	---	---	---	---	---	---	---	-----------	------------------------

Byte 19:

					I		I	OTTT:	~1 1
0	n	n	n	n	n	n	n	CHK>	Checksum.

Description:

This command sends the data from one device to another peer to peer.

SRC	$\overline{\mathrm{DSTL}}$	$\overline{\text{DSTH}}$	Comments
0x0F	0x08	0x00	Discover devices broadcast message.
0xoF	0x10	0x00	Discover device response.

Response:

OPC_PEER_XFER_20 for discover devices.

Notes:

The discover response decoded peer transfer message encodes as follows:

```
D1 IPL Version Number
```

- D2 Serial Number low byte
- D3 Serial Number high byte

D4

- D5 Serial Number 2 low byte
- D6 Serial Number 2 high byte

D7

D8

The IPL version number is encoded as follows:

- d6 version number bit 3
- d5 version number bit 2.
- d4 version number bit 1
- d3 version number bit 0
- d2 subversion number bit 2
- d1 subversion number bit 1
- d0 subversion number bit 0

e.g. 0x09 decodes as version 1.1.

These came from DigiPLII:

message Length = 20 e5 14 0f 10 00 24 00 00 00 02 00 08 07 00 00 00 00 00 38

 $message\ Length = 20\ e5\ 14\ 0f\ 10\ 00\ 24\ 00\ 00\ 00\ 00\ 00\ 57\ 13\ 00\ 00\ 00\ 00\ 00\ 71$

 $message \ Length = 20 \ e5 \ 14 \ 0f \ 10 \ 00 \ 1b \ 00 \ 00 \ 03 \ 02 \ 00 \ 54 \ 10 \ 00 \ 00 \ 00 \ 00 \ 00 \ 4f$

It reports PR4 with serial number 0x0788 ver 0 PR4 with serial 0x1357 ver 0 DCS240 with SN 0x0AAB ver 0.3 DCS210 with SN 0x10D4 ver 0.3

1.5.27 ReadCfgSlotData

Description:

This response provides the current command station configuration slot data. It is sent by the command station in response to the **ReqCfgSlotData** commands..

Group:

Variable-Byte Message

Opcode:

OPC_SL_RD_DATA

Type:

Response

Encoding:

Byte 0:

TITIO OF THE ONE.	1	1 1	0 0	1	1	1	0xE7	$\operatorname{Opcod}\epsilon$
-------------------	---	-----	-----	---	---	---	------	--------------------------------

Byte 1:

0	1	1	1	1	1	1	0	0x0E	Message length (14 bytes).
U	1	1	1	1	1	1	U	OXOL	message rength (14 by tes).

OST1 to OST6 encode the command station's option switch table. The narrative is based upon information in the the DCS210 and DCS240 user manuals. A bit value of 1 means that the switch is closed and a value of 0 means that a switch is thrown. OpSw 8, OpSw 16, OpSw 24, OpSw 32 and OpSw 40 cannot be read due to bit 7 being cleared in the message format. The manual shows these switches as defaulting to thrown, i.e. 0, and are flagged in all cases except OpSw 40 as "do not change".

Byte 2:

	0	1	1	1	1	1	1	1	0x7F	Configuration slot number.

${\bf 1.5.29} \quad {\bf ReqInterface Status}$

Description	•

Sent by a computer to request an **ReadInterfaceStatus** message from network interface device.

Group:

2-Byte Message

Opcode:

OPC_BUSY

Type:

Command

Applicable Hardware:

Digitrax PR4 and DCS240.

Encoding:

Byte 0:

1	0	0	0	0	0	0	1	0x81	Opcode
---	---	---	---	---	---	---	---	------	--------

Byte 1:

0	1 1	1	1	1	1	0	0x7E	Checksum
---	-----	---	---	---	---	---	------	----------

Response:

A Digitrax interface returns an **InterfaceStatus** message.

Signature:

None - the command is intercepted by the interface and is not passed on to the network.

Notes:

None.

1.5.30 OPC_RQ_SL_DATA

Operation: Request slot data or status block. Group: 4-Byte Message $\underline{\text{Direction:}} \rightarrow \text{Switch}$ Encoding: Byte 0: Opcode. 1 0 0 1 0xBB1 1 1 Byte 1: 0 <SLOT#>Slot number in the range 0x00 to n n n n \mathbf{n} n n 0x7F. 0 returns the command station status block Byte 2: 0 $d6 \mid 0$ d3d2 | d1 | d0 |<SLOTP> Bits d2 to d0 contain the extended 0 slot page number in the range 0x0 to 0x7. The bit d3 does something but its function is not yet known. When bit d6 is 1 then extended slot data is returned for all slots, when it is 0 standard slot data is returned for slots 0x00 to 0x7F. Byte 3: <CHK>Checksum. 0 \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} Description:

Request slot data or status block.

Response:

if SLOTP = 0x00 then OPC_SL_RD_DATA, otherwise OPC_SL_RD_DATA_EXT.

Notes:

None.

1.5.31 OPC_SLOT_STAT1

Operation: Set slot status 1. Group: 4-Byte Message Direction: \rightarrow Command Station Encoding: Byte 0: $1 \quad 0$ 0 1 0xB5Opcode. 1 1 Byte 1: 0 <SLOT#>Slot number in the range 0x00 to n \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} 0x7F.Byte 2: d6 d5d4 d3 d2 d1 d0<STAT1>Slot status 1. Byte 3: <CHK> Checksum. 0 n n n \mathbf{n} \mathbf{n} n n Description: This function sets the slot's status 1 values. Response: None. Notes: None.

1.5.32 OPC_SV_PROG

Operation: Program system variables. Variable-Byte Message Group: Direction: device \rightarrow device Encoding: Byte 0: 1 1 0 0 0 0xE5Opcode. 1 1 1 Byte 1: 0 0 0 0 1 0 0 0x14Message length (20 bytes). Byte 2: 0 n \mathbf{n} n \mathbf{n} n \mathbf{n} n <SRC>Source id in the range 0x00 to 0x7F.Byte 3: 0 <SV $_{-}$ CMD>Specifies the SV access type. n n n n \mathbf{n} n n Byte 4: 0 n \mathbf{n} n \mathbf{n} \mathbf{n} \mathbf{n} n <DSTH>Destination id high in the range 0x00 to 0x7F. Byte 5: 0 <HOST>Device host identifier. n \mathbf{n} \mathbf{n} n \mathbf{n} \mathbf{n} \mathbf{n}

This should be 0x00 for discover devices broadcast.

Response:

OPC_PEER_XFER_20 for discover devices.

Notes:

The discover response decoded peer transfer message encodes as follows:

```
D1 IPL Version Number
```

D2 Serial Number - low byte

D3 Serial Number - high byte

D4

D5 Serial Number 2 - low byte

D6 Serial Number 2 - high byte

D7

D8

The IPL version number is encoded as follows:

```
d6 version number bit 3
```

- d5 version number bit 2.
- d4 version number bit 1
- d3 version number bit 0
- d2 subversion number bit 2
- d1 subversion number bit 1
- d0 subversion number bit 0

e.g. 0x09 decodes as version 1.1.

These came from DigiPLII:

```
message Length = 20 e5 14 0f 10 00 24 00 00 00 02 00 08 07 00 00 00 00 00 00 38
```

 $message\ Length = 20\ e5\ 14\ 0f\ 10\ 00\ 24\ 00\ 00\ 00\ 00\ 00\ 57\ 13\ 00\ 00\ 00\ 00\ 00\ 71$

 $message \ Length = 20 \ e5 \ 14 \ 0f \ 10 \ 00 \ 1b \ 00 \ 00 \ 03 \ 02 \ 00 \ 54 \ 10 \ 00 \ 00 \ 00 \ 00 \ 00 \ 4f$

It reports PR4 with serial number 0x0788 ver 0 PR4 with serial 0x1357 ver 0 DCS240 with SN 0x0AAB ver 0.3 DCS210 with SN 0x10D4 ver 0.3

1.5.33 OPC_SW_ACK

Operation: Request switch command with acknowledge.

Group: 4-Byte Message

 $\underline{\text{Direction:}} \rightarrow \text{Turnout controller}$

Encoding:

Byte 0:

1	0	1	1	1	1	0	1	0xBD	Opcode.
---	---	---	---	---	---	---	---	------	---------

Byte 1:

0	d6	d5	d4	d3	d2	d1	d0	<sw1></sw1>	Switch address A6 to A0
---	----	----	----	----	----	----	----	-------------	-------------------------

- d6 A6.
- d5 A5.
- d4 A4.
- d3 A3.
- d2 A2.
- d1 A1.
- d0 A0.

Byte 2:

0	d6	d5	d4	d3	d2	d1	d0	$\langle SW2 \rangle$	Switch	address	A10	to	A7	and
	switch control bits.													

- d6 Reserved. Set to 0.
- d5 Direction. 1 means closed/green, and 0 means thrown/red.
- d4 Output. 1 means on, and 0 means off.
- d3 A10.
- d2 A9.
- d1 A8.
- d0 A7.

Byte 3:

0	n n n	n n n r	<chk></chk>	Checksu
---	-------	---------	-------------	---------

Description:

Command a turnout controller to a specified state and send acknowledge.

Response:

OPC_LONG_ACK.

Notes:

None.

OPC_SW_REP 1.5.34

Operation: Turnout sensor report.

Group: 4-Byte Message

Direction: Turnout sensor \rightarrow

Encoding:

Byte 0:

		0 1 0xB1	0	0	0	1	1	0	1	
--	--	----------	---	---	---	---	---	---	---	--

Byte 1:

0	d6	d5	d4	d3	d2	d1	d0	<sn1></sn1>	Sensor address
							02.0	1,0 = . = 2	

SN2.	d6 = 1	SN2.	d6 = 0
d6	A7.	d6	A6.
d5	A6.	d5	A5.
d4	A5.	d4	A4.

d2	A3.	d2	A2.
d1	A2.	d1	A1.
d0	A1.	d0	A0.

Byte 2:

SN2.d6 = 1

- Report type. 1 means the report is an input report, and 0 means the report is an output report.
- d5A0.
- d4 Input sensor state, 1 means sensor >= 6V, 0 means sensor= 0V.
- d3A11.
- A10. d2
- d1A9.
- d0A8.

SN2.d6 = 0

- Report type. 1 means the report is an input report, and 0 means the report is an output report.
- 0 means closed output line is off, 1 means the closed output line is on.
- d40 means thrown output line is off, 1 means the thrown output line is on.
- A10. d3
- d2A9.
- d1A8.
- d0A7.

Byte	3
DVIE	v.

0	n	n	n	n	n	n	n	<CHK $>$	Checksum.
---	---	---	---	---	---	---	---	----------	-----------

Description:

Turnout sensor report.

Response:

None.

Notes:

None.

$1.5.35 \quad OPC_SW_REQ$

Operation: Request switch command.

Group: 4-Byte Message

Direction: \rightarrow Turnout controller

Encoding:

Byte 0:

1	0	1	1	0	0	0	0	0xB0	Opcode.

Byte 1:

0	d6	d5	d4	43	d2	d1	90	<sw1></sw1>	Switch address A6 to A
0	ao	ao	u.i	ao	u_	u.i	u.o	\D 11 1/	5 WICCH dadress 110 to 1

- d6 A6.
- d5 A5.
- d4 A4.
- d3 A3.
- d2 A2.
- d1 A1.
- d0 A0.

Byte 2:

0	d6	d5	d4	d3	d2	d1	d0	<sw2></sw2>	Switch	address	A10	to	A7	and
									switch o	control bi	its.			

- d6 Reserved. Set to 0.
- d5 Direction. 1 means closed/green, and 0 means thrown/red.
- d4 Output. 1 means on, and 0 means off.
- d3 A10.
- d2 A9.
- d1 A8.
- d0 A7.

Byte 3:

+0+1	n	n	n	n	n	n	n	<CHK $>$	Checksum.
------	---	---	---	---	---	---	---	----------	-----------

Description:

Command a turnout controller to a specified state.

Response:

OPC_LONG_ACK if command failed, otherwise no response.

Notes:

The on power on the command station sends a sequence of OPC_SW_REQ messages with the following values of SW1 and SW2:

$\underline{\mathrm{SW1}}$	$\underline{\mathrm{SW2}}$	Purpose
0x78	0x27	
0x79	0x27	
0x7A	0x27	
0x7B	0x27	
0x78	0x07	Interrogate all PM4 inputs?
0x79	0x07	Interrogate all BDL16 input reports?
0x7A	0x07	Interrogate all SE8 input reports?
0x7B	0x07	Interrogate all DS64 input reports.

1.5.36 OPC_SW_STATE

Operation: Request state of switch.

Group: 4-Byte Message

 $\underline{\text{Direction:}} \rightarrow \text{Switch}$

Encoding:

Byte 0:

1	0	1	1	1	1	0	0	0xBC	Opcode.
			_		_	0		OND	Opecac

Byte 1:

--	---	-------	-------	-------------	----------------------

Byte 2:

0	d6	d5	d4	d3	d2	d1	d0	<sw2></sw2>	Switch	address	A10	to	A7	and
									switch o	control bi	its.			

- d6 Reserved. Set to 0.
- d5 Direction. 1 means closed/green, and 0 means thrown/red.
- d4 Output. 1 means on, and 0 means off.
- d3 A10.
- d2 A9.
- d1 A8.
- d0 A7.

Byte 3:

()	n	n	n	n	n	n	n	<CHK $>$	Checksum.
---	---	---	---	---	---	---	---	---	----------	-----------

Description:

Request state of switch.

Response:

OPC_LONG_ACK.

Notes:

This needs to be tested to see what the real purpose is.

$1.5.37 \quad OPC_TRANS_REP$

Operation: Transponder input report.

Group: 6-Byte Message		
$\underline{\text{Direction:}} \ \to \text{Command Station}$		
Encoding:		
Byte 0:		
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	0xD0	Opcode.
Byte 1:		
		A value of $0x20$ means the positive detection of a transponder, $0x00$ means no longer detected.
Byte 2:		
0 0 0 0 n n n n	<ZONE# $>$	Zone indicator $(0x0 = A, 0x2 = B 0x4 = C, 0x6 = D)$.
Byte 3:		
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	<adr></adr>	Locomotive address low bits.
Byte 4:		
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	<ADR2 $>$	Locomotive address high bits.
Byte 5:		
	<chk></chk>	Checksum.
Description:		
Response:		
None.		
Notes:		
None.		

1.5.38 OPC_UNLINK_SLOTS

Operation: Unlink slots. Group: Variable-Byte Message Direction: \rightarrow Command Station Encoding: Byte 0: $1 \quad 0$ 0 0 0 0xB8Opcode. 1 1 Byte 1: 0 <SL1> Slot number in the range 0x00 to n n n \mathbf{n} n \mathbf{n} \mathbf{n} 0x7F.Byte 2: Slot number in the range 0x00 to $\langle SL2 \rangle$ 0 n \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} n 0x7F.Byte 3: 0 Checksum. n <CHK>n \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} Description: This command unlinks slot SL1 from slot SL2. Response: Returns OPC_SL_RD_DATA or OPC_LONG_ACK. Notes: None.

1.5.39 OPC_WR_SL_DATA_EXT

Operation: Write extended slot data. Variable-Byte Message Group: <u>Direction</u>: Command Station \rightarrow Encoding: Byte 0: $1 \quad 1$ 0 0xEEOpcode. 1 0 1 1 1 Byte 1: 0 0 1 0 0 1 0x15Message length (21 bytes). 1 Bytes 2 to 19 encode as per extended slot bytes 0 to 17. Byte 20: 0 <CHK>Checksum. n \mathbf{n} \mathbf{n} \mathbf{n} n n \mathbf{n} Description: This command sends the slot data to the command station. Response: Returns OPC_LONG_ACK. Notes: None.

1.5.40 WriteStdSlotData

Description:

This command writes the standard slot data for the specified slot to the command station.

Group:

Variable-Byte Message

Opcode:

OPC_WR_SL_DATA

Type:

Command

Encoding:

Byte 0:

1 1 1 0 1 1 1 1	0xEF	Opcode.
Byte 1:		
0 1 1 1 1 1 1 0	0x0E	Message length (14 bytes).
Byte 2:		
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	<slot#></slot#>	Slot number in the range $0x00$ to $0x77$. Slot $0x00$ is the dispatch special slot.

Chapter 2

Fast Clock

2.1 Summary

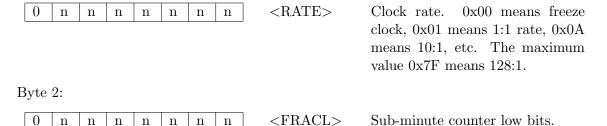

The command station provides a system fast clock and parameters are stored in slot #123 (0x7B). Use OPC_WR_SL_DATA to write new clock information, The current slot information can be read using OPC_RQ_SL_DATA. This will return an OPC_SL_RD_DATA message containing the fast clock information. This message is called the "sync". Other throttles will update to this sync. Note that all attached display devices keep a current clock calculation based on this sync read value, i.e. devices must not continuously poll the clock slot to generate time, but use this merely to restore sync and follow current rate etc. The clock slot is typically "pinged" or read every 70 to 100 seconds, by a single user, so all attached devices can synchronise any phase drifts. Upon seeing a sync read, all devices should reset their local sub-minute phase counter and invalidate the sync update ping generator.

2.2 Slot #123 Encoding

Byte 0:

0	1	1	1	1	0	1	1

Byte 1:

Byte 3:

The implementation and meaning of FRACL and FRACH depend upon the specific clock generator. These values should not be used externally. These values are reset when a valid sync message is seen.

That said, the following timing was derived for the DCS240.

Get:

$$\label{eq:maxTick} \begin{split} \max & Tick = 0xBFF \\ ticks = \max & Tick - (0x3FFF - ((\& 0x7F) -- ((\& 0x7F) << 7))) \\ seconds = 60.0 * ticks / (maxTick + 1) \\ Set: \end{split}$$

$$temp = ticks - maxTick + 0x3FFF$$

$$\langle FRACL \rangle = temp \& 0x7F$$

$$\langle FRACH \rangle = (temp >> 7) \& 0x7F$$

Byte 4:

0	n	n	n	n	n	n	n	<MINS $>$	Fast clock minutes.	This is en-
									coded.	

Get:

temp =
$$((255 - \langle MINS \rangle) \& 0x7F) \mod 60$$

minutes = $(60 - \text{temp}) \mod 60$

Set:

$$<$$
MINS $> = (255 - (60 - minutes)) & 0x7F$

Byte 5:

95

d6 Reserved. Set to 0.									
d5 Reserved. Set to 0.									
d4 Reserved. Set to 0.									
d3 1 means the programming track is busy.									
d2 1 means this master implements the Network version									
1.1 capability, 0 means the master is a DT200.									
d1 0 means the track is paused, broadcast an emergency									
stop. d0 1 means the DCC packets are on in the master, global									
power up.									
Byte 6:									
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$									
Get:									
temp = $((256 - \langle HRS \rangle) \& 0x7F) \mod 24$									
$hours = (24 - temp) \mod 24$									
Set:									
<HRS $> = (256 - (24 - hours)) & 0x7F$									
Byte 7:									
DAYO DAYO									
0 n n n n n n n SDAYS> Fast clock days. Number of 24 hour clock rolls.									
Byte 8:									
$\begin{bmatrix} 0 & d6 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$ < CNTRL> The bit d6 indicates valid clock in-									
formation. 1 means good and 0 means ignore.									
Byte 9:									
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$									
Byte 10:									
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$									

ID1 and ID2 indicate the device that last set the clock. 0x00, 0x00 means that not set has happened. 0x7F, 0x7X are reserved for computer use.

Chapter 3

Updating Firmware

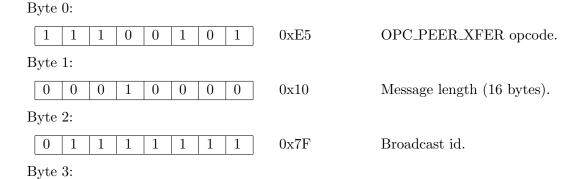

3.1 Bootloader Protocol 1

3.2 Bootloader Protocol 2

- 1. The IPL Setup message is sent twice to initiate the download.
- 2. Each block is sent,
- 3. The IPL End Operation message is sent.

A block consists of an IPL Address message following by 1 or more IPL Data messages.

3.2.1 IPL Setup

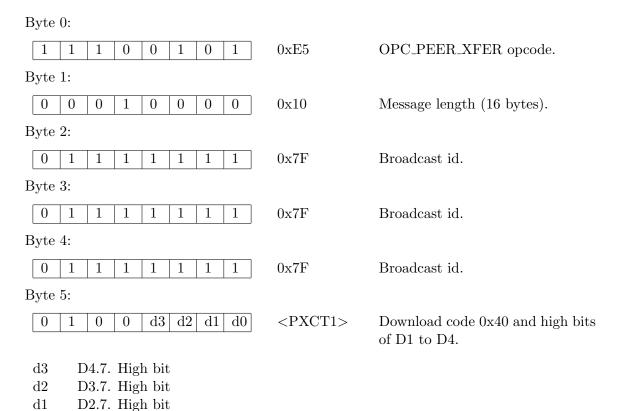

Byte 12:

$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	0x7F	Broadcast id.
Byte 4:		
0 1 1 1 1 1 1 1	0x7F	Broadcast id.
Byte 5:		
0 1 0 0 d3 d2 d1 d0	<pxct1></pxct1>	Download code 0x40 and high bits of D1 to D4.

3.4 DMF File Format

The manufacturer's DMF file format is a modified form of the Intel Hexadecimal Object File Format. Character encoding is ASCII. The file consists of multiple "records" each terminated by an ASCII linefeed character (0x0A). There are four types of record and they appear in the file in the following order:

- 1. Sync records
- 2. Parameter records
- 3. Data records
- 4. End of File record

3.4.1 Sync Records

Sync records are used to identify the file as a DMF file. There are six sync records each consisting of a single ASCII # character (0x23).

Example:

#

#

#

#

3.4.2 Parameter Records

PARAM MARK	PARAMETER NAME	NAME TERMINATOR	VALUE
! (0x21) < SPC > (0x20)	ASCII text	: (0x3A) < SPC > (0x20)	decimal value
2 bytes	variable bytes	2 byte	variable bytes

PARAMETER RECORD FORMAT

Parameter records start with a two byte PARAM MARK. This consists of the ASCII code for the exclamation mark (0x21) followed by the ASCII code for the space character (0x20). The PARAMETER NAME is next. The PARAMETER NAME is ASCII encoded text identifying the parameter. The PARAMETER NAME may include spaces. It is terminated by the NAME TERMINATOR which consists of the ASCII code for a colon

(0x3A) followed by the ASCII code for a space character (0x20). The last field is the VALUE field. This is a decimal numeric value encoded as ASCII text.

The following parameters have been identified and they are presented in the following order (it is not known if the order is significant):

- 1. Bootloader Version
- 2. Manufacturer Code
- 3. Product Code
- 4. Hardware Version
- 5. Software Version
- 6. Chunk Size
- 7. Delay
- 8. Options
- 9. First Address
- 10. Last Address
- 11. Prog Blk Size
- 12. Erase Blk Size
- 13. Erase Dly

Example:

- ! Bootloader Version: 2 ! Manufacturer Code: 0
- ! Product Code: 88
- ! Hardware Version: 0
- ! Software Version: 2
- ! Chunk Size: 64
- ! Delay: 50
- ! Options: 2
- ! First Address: 24576 ! Last Address: 73728
- ! Prog Blk Size: 256
- ! Erase Blk Size: 2048
- ! Erase Dly: 100

3.4.3 Data Records

RECORD MARK	RECLEN	LOAD OFFSET	RECTYP	DATA	CHKSUM
(:)					
1 byte	2 bytes	6 bytes	2 bytes	n bytes	2 bytes

DATA RECORD FORMAT

The data record provides a set of hexadecimal digits that represent the ASCII code for data bytes that make up a portion of a memory image.

Each data record begins with a RECORD MARK field containing the ASCII code for the colon (:) character (0x3A).

Each record has a RECLEN field which specifies the number of bytes of data which follows the RECTYP field of the record. Note that one data byte is represented by two ASCII characters. The maximum value of the RECLEN field is hexadecimal "FF" or 255. Although the maximum is 255, the manufacturer seems to prefer 64.

Each record has a LOAD OFFSET field which specifies the 24-bit starting load offset of the data bytes.

The RECTYP field for data records is "00".

Each record has a variable length DATA field, it consists of zero or more bytes encoded as pairs of hexadecimal digits.

Each record ends with a CHKSUM field that contains the ASCII hexadecimal representation of the two's complement of the 8-bit bytes that result from converting each pair of ASCII hexadecimal digits to one byte of binary, from and including the RECLEN field to and including the last byte of the DATA field. Therefore, the sum of all the ASCII pairs in a record after converting to binary, form the RECLEN field up to and including the CHKSUM field, is zero.

The contents of the individual fields within the record are:

RECORD MARK This field contains 0x3A, the encoding of the ASCII colon

(:) character.

RECLEN The field contains two ASCII hexadecimal digits that specify

the number of data bytes in the record. The maximum value

is "FF" or 0x4646 (255 decimal).

LOAD OFFSET This field contains six ASCII hexadecimal digits representing

the address at which the first byte of the data is to be placed.

Most significant digit is presented first.

RECTYP This field contains 0x3030, the hexadecimal encoding of the

ASCII characters "00", which specifies the record type to be

a data record.

DATA This field contains pairs of ASCII hexadecimal digits, one

pair for each data byte.

CHKSUM This field contains the check sum on the RECLEN, LOAD

OFFSET, RECTYP, and DATA fields.

Example:

:400060000057AAC3880FAAC388559AC38855AAC388553AC38855AAC38855AAC3884AO 0C38855AAC38855AAC3882DFCC38861B8C3882DFCC38861B8C3886D

3.4.4 End of File Record

RECORD MARK	RECLEN	LOAD OFFSET	RECTYP	CHKSUM
(:)	"00"	"000000"	"01"	"FF"
1 byte	2 bytes	6 bytes	2 bytes	2 bytes

END OF FILE RECORD FORMAT

The End of File Record specifies the end of the file.

The contents of the individual fields within the record are:

RECORD MARK This field contains 0x3A, the encoding of the ASCII colon

(:) character.

RECLEN The field contains 0x3030, the hexadecimal encoding of the

ASCII characters "00". Since this record does not contain

any DATA bytes, the length is zero.

LOAD OFFSET This field contains 303030303030H, the hexadecimal encod-

ing of the ASCII characters "000000", since this field is not

used for this record.

RECTYP This field contains 0x3031, the hexadecimal encoding of the

ASCII characters "01", which specifies the record type to be

an End of File Record.

CHKSUM This field contains the check sum on the RECLEN, LOAD

OFFSET, and RECTYP fields. Since all the fields are static, the check sum can also be calculated statically, and the value is 4646H, the hexadecimal encoding of the ASCII characters

"FF".

Example:

:000000001FF
