Chapter 1

The Network Protocol

.

1.1 Overview

Loconet is a peer to peer distributed network system on which all devices can monitor the network data flow. The network is event driven by different devices in time, and is not polled by a centralised controller in normal operation. The normal the network state is idle, with no data traffic unless a device has information to send. With no traffic flow, the network is quiet.

The network data is sent in asynchronous format using 1 start bit, 8 data bits and 1 stop bit. The 8 bit data is transmitted least significant bit first. The bit times are 60.0 μ S or 16,660 baud +/- 1.5%. A computer can connect to a Digitrax USB interface at higher baud rates and the device will make the necessary conversion. Bytes may be transmitted back-to-back, with a start bit immediately following the stop bit of the previous character.

Any message that has format or framing errors, data errors or is a fragment caused by noise glitches and does not completely follow the message format will be ignored by all receivers, and a new opcode will be scanned for re-synchronisation.

The OPC_BUSY opcode is included to allow the master to keep the network active whilst it is performing a task that requires a response, and entails a significant processing delay, i.e. it can ensure no new requests are started until it has responded to the last message. This OPC_BUSY opcode should be simply stripped and ignored.

If a device disconnects from the network and so does not access or reference a slot within the system purge time, the command station will force the un-accessed slot to common status

so other system devices can use the slot. The typical purge time of a command station is about 200 seconds. A good "ping" or slot update activity is about every 100 seconds, i.e. if a user makes no change to a throttle/slot within 100 seconds, the throttle/device should automatically send another speed update at the current speed to reset the purge timeout for that slot.

1.2 Message Format

All the network communications are via multi-byte messages. The command station is defined as the device that is maintaining the refresh stack for DCC packet generation and is actively generating the DCC track data. Refresh of information is typically only performed for mobile decoders. Stationary type decoders are not refreshed and individual immediate commands are sent out to the track as requested.

The command station is only privileged in respect to performing the task of maintaining the locomotive refresh stack and generating DCC packets. In this way other network transactions may occur that the command station does not need to be involved with or understand, as long as they follow the message protocol and timing requirements. i.e. other devices may have a dialog on the network without disturbing or involving the command station. Devices on the network monitor the messages, check for format and data integrity and parse good messages to decode if action is required in the context. Devices such as throttles, input sensors, computer interfaces and control panels may generate the network messages without needing prompting or polling by a central controller.

Devices frequently will be added and removed from an operating the network. The devices and protocol are tolerant of electrical and data transients. The format chosen gives a good degree of data integrity, guaranteed quick network-state synchronisation, high data throughput, good distribution of access to many competing devices and low event latency. Also, the devices may be operated without need for unique ID or other requirements that can make network administration awkward.

The data bytes on the Network are defined as 8 bit data with the most significant bit as an opcode flag bit. If the most significant bit, d7, is 1 then the 7 least significant bits are interpreted as a network opcode. The opcode byte may only occur once in a valid message and is the first byte of a message. All the remaining bytes in the message must have a most significant bit of 0, including the last checksum byte. The checksum is the 1's complement of the byte wise exclusive or of all the bytes in the message, except the checksum itself. To validate data accuracy, all the bytes in a correctly formatted message are exclusive or'ed. If this resulting byte value is 0xFF, then the message data is accepted as good.

The opcodes may be examined to determine message length and if subsequent response

message is required. Data bits d6 and d5 encode the message length. The message length includes the opcode and the checksum bytes. The bit d3 = 1 implies that a follow-on message or reply is expected.

d7	$\underline{d6}$	$\underline{\mathrm{d}5}$	$\underline{\mathrm{d}4}$	$\underline{d3}$	$\underline{d2}$	$\underline{d1}$	$\underline{d0}$	
1	0	0	\mathbf{E}	D	\mathbf{C}	В	A	2 byte message
1	0	1	\mathbf{E}	D	\mathbf{C}	В	A	4 byte message
1	1	0	\mathbf{E}	D	\mathbf{C}	В	A	6 byte message
1	1	1	\mathbf{E}	D	\mathbf{C}	В	A	Variable length message. The
								next byte in the message is a 7
								bit byte count.

The A,B,C,D,E are bits available to encode 32 opcodes per message length.

1.3 Refresh Slots

The command station standard refresh stack is an array of up to 120 read/write refresh slots. The slot address is a principal component and is generally the second byte or 1st argument of a message to the master. The standard refresh slot contains up to 10 data bytes relating to a locomotive and also controls a task in the track DCC refresh stack. Most mobile decoder or locomotive operations process the slot associated with the locomotive to be controlled. The slot number is a similar shorthand ID# to a file handle. Slot addresses 120-127 are reserved for system and command station control. Slot #124 (0x7C) is allocated for read/write access to the programming track, and the format is not the same as a standard slot. The DCS240 command station has 400 read/write refresh slots. The additional slots in excess of the 120 standard slots are accessed by using extended opcodes. The DCS210 also supports the extended opcodes though it only has 100 refresh slots.

1.3.1 Slot Format

Standard Slot - 0 to 119

Byte 0:

Slot number in the range 0x00 to 0x7F. Slot 0x00 is a special slot, and slots in the range 0x70 to 0x7F are reserved to Digitrax.

Byte 1:

and 0x01 means emergency stop. Other values mean increasing

speed.

d7	$d6 \mid d5$	d4	$d3 \mid d2 \mid d1 \mid d0$ <stat1></stat1>	Slot status 1.					
	d7	d6							
	0	$\frac{as}{0}$	— — — — — — — — — — — — — — — — — — —						
	0	1	Consist sub-member.						
	1	0	Consist top-member.						
	1	1	Consist Mid-Consist member.						

Note: d7 is set to 0 in the message by the command station and so may not correctly reflect the actual setting in the slot table.

	$\frac{d5}{0}$ 0 1	$\begin{array}{c} \underline{d4} \\ 0 \\ 1 \\ 0 \\ 1 \end{array}$	Free slot, no valid data. Not refreshed. Common. Locomotive address in this slot. Refreshed. Idle. Locomotive address in this slot. Not refreshed. In Use. Locomotive address in this slot. Refreshed.
		<u>d3</u> 0 1	No slot consist linked into this slot. Slot consist linked into this slot.
$\underline{d2}$	<u>d1</u>	$\underline{d0}$	
0	0	0	28 step decoder. 3-byte packet regular mode
0	0	1	28 step decoder. Generate trinary packets for this mobile address
0	1	0	14 step decoder.
0	1	1	128 step decoder.
1	0	0	28 step decoder. Allow advanced consisting
1	0	1	reserved
1	1	0	reserved
1	1	1	128 step decoder. Allow advanced consisting
Byte	2:		
0	n n	n n	$\begin{array}{c ccccccccccccccccccccccccccccccccccc$
Byte	3:		
0	n n	n n	$\begin{array}{c ccccccccccccccccccccccccccccccccccc$

Byte 4:

1.3. REFRESH SLOTS

5

- d6 Reserved. Set to 0.
- d5 Locomotive direction. 1 means forward, 0 means backwards.
- d4 F0 state. 1 means on, and 0 means off.
- d3 F4 state. 1 means on, and 0 means off.
- d2 F3 state. 1 means on, and 0 means off.
- d1 F2 state. 1 means on, and 0 means off.
- d0 F1 state. 1 means on, and 0 means off.

Byte 5:

ſ	Ω	d6	45	44	43	49	41	40	<trk></trk>	Clobal system track status
	U	ao	aə	a_4	a a	az	a I	au	<1KK>	Global system track status.

- d6 Reserved. Set to 0.
- d5 Reserved. Set to 0.
- d4 Reserved. Set to 0.
- d3 1 means the programming track is busy.
- d2 1 means this master implements the Network version 1.1 capability, 0 means the master is a DT200.
- d1 0 means the track is paused, broadcast an emergency stop.
- d0 1 means the DCC packets are on in the master, global power up.

Byte 6:

0	10	1 -	14	d3	10	11	10	<000s	CI I I I O

<ID1>

Slot 0x7F

OST1 to OST6 encode the command station's option switch table. The narrative is based upon information in the the DCS210 and DCS240 user manuals. A bit value of 1 means that the switch is closed and a value of 0 means that a switch is thrown. OpSw 8, OpSw 16, OpSw 24, OpSw 32 and OpSw 40 cannot be read due to bit 7 being cleared in the message format. The manual shows these switches as defaulting to thrown, i.e. 0, and are flagged in all cases except OpSw 40 as "do not change".

Byte 15:

1.4 Standard Address Selection

To request a mobile or locomotive decoder task in the refresh stack, a throttle device requests a locomotive address for use (OPC_LOCO_ADR). The command station responds with a slot data read for the slot (OPC_SL_RD_DATA), that contains this locomotive address and all of its state information. If the address is currently not in any slot, the command station will load this new locomotive address into a new slot (speed=0, direction

forwards, functions off and 128 step mode) and return this as a OPC_SL_RD_DATA. If no inactive slots are free to load the new locomotive address, the response will be the OPC_LONG_ACK with a fail code 0x00.

The throttle/computer must then examine the slot data bytes to work out how to process the command station response. If the slot status 1 byte shows the slot to be common idle or new the throttle may change the slot to in use by performing a null move instruction (see OPC_MOVE_SLOTS) on this slot. This activation mechanism is used to guarantee proper slot usage interlocking in a multi-user asynchronous environment.

If the slot return information shows the locomotive requested is in use or up-consisted (i.e. the SL_CONUP, bit 6 of slot status 1=1) the user should not use the slot. Any up-consisted locomotives must be unlinked before usage. Always process the result from the OPC_LINK_SLOTS and OPC_UNLINK_SLOTS commands, since the command station reserves the right to change the reply slot number and can reject the linking tasks under several circumstances. Verify the reply slot number and the link UP/DN bits in slot status 1 are as you expected.

The throttle will then be able to update speed, direction and function information. Whenever slot information is changed in an active slot, the slot is flagged to be updated as the next DCC packet sent to the track. If the slot is part of linked consist slots the whole consist chain is updated consecutively.

If a throttle is disconnected from the Network, upon reconnection (if the throttle retains the slot state from before disconnection) it will request the full status of the slot it was previously using. If the reported status and speed, function data etc., from the command station exactly matches the remembered slot state the throttle will continue using the slot. If the slot data does not match, the throttle will assume the slot was purged free by the system and will go through the setup log on procedure again.

With this procedure the throttle does not need to have a unique ID number. slot addresses do not imply they contain any particular locomotive address. The system can be mapped such that the slot address matches the locomotive address within, if the user directly reads and writes to slots without using the command station to allocate locomotive addresses.

1.5 Opcodes

1.5. OPCODES

OPC_BRD_OPSW

Operation: Read and write board option switches.

Group: 6-Byte Message

 $\underline{\text{Direction:}} \rightarrow \text{Command Station}$

Encoding:

Byte 0:

1	1	0	1	0	0	0	0	0xD0	Opcode.
---	---	---	---	---	---	---	---	------	---------

Byte 1:

$ \begin{array}{ c c c c c c c c c c c c c c c c c c c$	The bit d0 is the most signifi-
	cant bit of the board id. Bit d4
	indicates read/write direction. 1

means write and 0 means read.

Byte 2:

Byte 3:

PM4 0x70.

BDL16 0x71.

SE8C 0x72.

DS64 0x73.

Byte 4:

0	d6	d5	d4	d3	d2	d1	d0	Byte and bit number. The high
								nibble encodes the byte number,
								and the low nibble the bit number.

The byte number is calculated as (OpSw# - 1) >> 3 and the bit number is (OpSw# - 1) - byte number \times 8.

Byte 5:

0	n n n	n n n	<chk></chk>	Checksur
---	-------	-------	-------------	----------

Description:

Response:
OPC_LONG_ACK.
Notes:
None.
OPC_BUSY
Operation: Indicates that the master is busy.
Group: 2-Byte Message
$\underline{\text{Direction:}} \ \leftrightarrow \text{Command Station}$
Encoding:
Byte 0:
1 0 0 0 0 1 0x81 Opcode.
Byte 1:
0 1 1 1 1 1 0 0x7E Checksum.
Description:
This message indicates that the master is busy. When sent to a command station it responds with an OPC_PEER_XFER message.
Response:
None.

OPC_CONSIST_FUNC

Notes:

None.

Operation: Set function bits in a consist uplink element.

Group: 4-Byte Message

Direction: \rightarrow Command Station Encoding: Byte 0: 1 0 1 0 0xB6Opcode. 0 Byte 1: 0 <SLOT#>Slot number in the range 0x00 to n \mathbf{n} \mathbf{n} \mathbf{n} n \mathbf{n} \mathbf{n} 0x7F.Byte 2: d6 d5 d4 d3 d2 d1 d0 0 <DIRF> Consist element's direction and state of functions F0 to F4. d6Reserved. Set to 0. d5Locomotive direction. 1 means forward, 0 means backwards. d4F0 state. 1 means on, and 0 means off. F4 state. 1 means on, and 0 means off. d3d2F3 state. 1 means on, and 0 means off. d1F2 state. 1 means on, and 0 means off. d0F1 state. 1 means on, and 0 means off. Byte 3: 0 <CHK> Checksum. n \mathbf{n} \mathbf{n} n \mathbf{n} \mathbf{n} n Description: This function sets the consist element's direction and function F0 to F4 states. Response: None. Notes: None.

OPC_GPOFF

Operation: Global power off request.

2-Byte Message Group: Direction: \rightarrow Command Station Encoding: Byte 0: Opcode. 1 0 0 0 0 0 1 0 0x82Byte 1: Checksum. 1 0x7D1 1 1 1 0 1 Description: This command turns off the track power. Response: None. Notes: None. $\mathbf{OPC}_{\text{-}}\mathbf{GPON}$ Operation: Global power on request. 2-Byte Message Group: Direction: \rightarrow Command Station Encoding: Byte 0: Opcode. 1 0 0 0 0 0 1 0x83Byte 1: 0 Checksum. 1 1 1 1 0 0 0x7C1 Description:

This command sends a global power on request.

Response:

1.5. OPCODES 21

The on power on the command station sends an OPC_RQ_SL_DATA message for slot 0x7F. It also sends a sequence of OPC_SW_REQ messages with the following values of SW1 and SW2:

```
SW1
        SW2
               Purpose
 0x78
        0x27
 0x79
        0x27
 0x7A
        0x27
 0x7B
        0x27
 0x78
        0x07
               Interrogate all PM4 inputs?
 0x79
        0x07
               Interrogate all BDL16 input reports?
 0x7A
        0x07
               Interrogate all SE8 input reports?
 0x7B
        0x07
               Interrogate all DS64 input reports.
Notes:
None.
```

OPC_IDLE

Operation: Force idle state and broadcast emergency stop.

Group: 2-Byte Message

Direction: \rightarrow Command Station

Encoding:

Byte 0:

	1	0	0	0	0	1	0	1	0x85	Opcode.
В	yte	1:								

0

0

1

This command forces the Network into the idle state and broadcasts an emergency stop.

0x7A

Checksum.

Response:

None

Notes:

None.

OPC_IMM_PACKET

Operation: Send n-byte packet immediate.

Group: Variable-Byte Message

 $\underline{\text{Direction:}} \rightarrow \text{command station}$

Encoding:

OPC_LINK_SLOTS

Operation: Link slots.

4-Byte Message Group: Direction: \rightarrow Command Station Encoding: Byte 0: $1 \quad 0$ 1 1 0xB9Opcode. Byte 1: 0 n \mathbf{n} n n \mathbf{n} \mathbf{n} $\langle SL1 \rangle$ Slot number in the range 0x00 to 0x7F.Byte 2: 0 n n n n \mathbf{n} \mathbf{n} \mathbf{n} $\langle SL2 \rangle$ Slot number in the range 0x00 to 0x7F.Byte 3: Checksum. <CHK>0 n \mathbf{n} \mathbf{n} n \mathbf{n} \mathbf{n} n Description: This function links slot SL1 to slot SL2. The command station setsSL_CONUP/DN flags

appropriately. Invalid link will return a fail acknowledgement. Response:

OPC_SL_RD_DATA or OPC_LONG_ACK.

Notes:

None.

OPC_LOCO_ADR

Operation: Request a slot number for a locomotive.

Group: 4-Byte Message

 $\underline{\text{Direction:}} \rightarrow \text{Command Station}$

Encoding:

Byte 0:

	1	0	1	1	1	1	1	1	0xBF	Opcode.
Ε	Byte	1:								
	0	n	n	n	n	n	n	n	<adr2></adr2>	High address.
Ε	Byte	2:								
	0	n	n	n	n	n	n	n	ADR>	Low address.
Ε	Byte	3:								
	0	n	n	n	n	n	n	n	<chk></chk>	Checksum.

Description:

This message requests the slot number for the selected locomotive address. If the locomotive is found in the slot table then the command station returns an OPC_SL_RD_DATA message with the slot information. If it is not found then the command station will put the locomotive into a free slot and then return an OPC_SL_RD_DATA message with the slot information. If there are no free slots then the command station returns an OPC_LONG_ACK error code.

Note that regular short 7 bit NMRA addresses are denoted by $\langle ADR2 \rangle = 0$. The Analog, zero stretched, locomotive is selected when both $\langle ADR2 \rangle = 0$ and $\langle ADR \rangle = 0$. $\langle ADR \rangle$ is always a 7 bit value. If $\langle ADR2 \rangle$ is non-zero then the master will generate NMRA type 14 bit or long address packets using all 14 bits from $\langle ADR2 \rangle$ and $\langle ADR \rangle$ with $\langle ADR2 \rangle$ being the most significant address bits. Note that a DT200 Master does not process 14 bit address requests and will consider the $\langle ADR2 \rangle$ to be zero. You can check the $\langle TRK \rangle$ return bits to see if the master is a DT200.

Response:

OPC_SL_RD_DATA if success, otherwise OPC_LONG_ACK.

Notes:

The the Network 1.1 specification specifies that $\langle ADR2 \rangle$ value is 0x00.

OPC_LOCO_ADR_EXT

Operation: Request an extended slot for a locomotive.

Group: 4-Byte Message

Direction: \rightarrow Command Station Encoding: Byte 0: 1 0 0 0xBEOpcode. 1 Byte 1: 0 <ADR2>High address. n \mathbf{n} \mathbf{n} n \mathbf{n} \mathbf{n} \mathbf{n} Byte 2: <ADR> Low address. 0 n \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} \mathbf{n} n Byte 3: <CHK> Checksum. 0 n n n \mathbf{n} \mathbf{n} n n Description: This message requests the slot number for the selected locomotive address. If the locomotive is found in the slot table then the command station returns an OPC_SL_RD_DATA_EXT message with the slot information. If it is not found then the command station will put the locomotive into a free slot and then return an OPC_SL_RD_DATA_EXT message with the slot information. If there are no free slots then the command station returns an OPC_LONG_ACK error code. Note that regular short 7 bit NMRA addresses are denoted by $\langle ADR2 \rangle = 0$. The Analog, zero stretched, locomotive is selected when both $\langle ADR2 \rangle = 0$ and $\langle ADR \rangle = 0$. $\langle ADR \rangle$ is always a 7 bit value. If <ADR2> is non-zero then the master will generate NMRA type 14 bit or long address packets using all 14 bits from <ADR2> and <ADR> with <ADR2> being the most significant address bits. Note that a DT200 Master does not process 14 bit address requests and will consider the <ADR2> to be zero. You can check the <TRK> return bits to see if the master is a DT200. Response: OPC_SL_RD_DATA_EXT if success, otherwise OPC_LONG_ACK. Notes: None.

OPC_LOCO_DIRF

${\bf Description:}$

This command sends the data from one device to another peer to peer.

$\underline{\operatorname{SRC}}$	$\overline{\mathrm{DSTL}}$	$\overline{\mathrm{DSTH}}$	Comments
0x00			Source is command station.
Don't Care	0x00	0x00	Broadcast Message.
0x70 to $0x7E$			Reserved.
0x7F	0x00	0x00	Broadcast throttle message transfer.
0x7F	ID1	ID2	Throttle message transfer. ID1 and ID2 en-
			code ID.

Response:

None

Notes:

None.

$OPC_PEER_XFER_20$

Operation: Move bytes peer to peer.

Group: Variable-Byte Message

 $\underline{\text{Direction:}} \quad \text{device} \rightarrow \text{device}$

Encoding:

Byte 0:

	0xE5	Opcode.
Byte 1:		
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	0x14	Message length (20 bytes).
Byte 2:		
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	$\langle SRC \rangle$	Source id in the range 0x00 to

0x7F.

Byte 3:

Byte 14:

0	n	n	n	n	n	n	n	<pxct2></pxct2>	Data type code and high bits for
									D5 to D8.

- d6 XC5. Data type code.
- d5 XC4. Data type code.
- d4 XC3. Data type code.
- d3 D8.7. High bit
- d2 D7.7. High bit
- d1 D6.7. High bit
- d0 D5.7. High bit

$\underline{\mathrm{XC5}}$	$\underline{\text{XC4}}$	$\underline{\text{XC3}}$	Meaning
0	0	0	ANSI text string.
0	0	1	reserved.
0	1	0	reserved.
0	1	1	reserved.
1	0	0	reserved.
1	0	1	reserved.
1	1	0	reserved.
1	1	1	reserved.

Byte 15:

0	n	n	n	n	n	n	n	<d5></d5>	Data item 5. Low 7 bits	١.
---	---	---	---	---	---	---	---	-----------	-------------------------	----

Byte 16:

	0	n	n	n	n	n	n	n	<d6></d6>	Data item 6	Low 7 b	oits.
--	---	---	---	---	---	---	---	---	-----------	-------------	---------	-------

Byte 17:

Byte 18:

0	n	n	n	n	n	n	n	<d8></d8>	Data item 8.	Low 7 bits	١.
---	---	---	---	---	---	---	---	-----------	--------------	------------	----

Byte 19:

0	n	n	n	n	n	n	n	<chk></chk>	Checksum.

Description:

This command sends the data from one device to another peer to peer.

$\underline{\operatorname{SRC}}$	$\overline{\mathrm{DSTL}}$	$\overline{\mathrm{DSTH}}$	Comments
0x0F	0x08	0x00	Discover devices broadcast message.
0xoF	0x10	0x00	Discover device response.

Response:

OPC_PEER_XFER_20 for discover devices.

Notes:

The discover response decoded peer transfer message encodes as follows:

- D1 IPL Version Number
- D2 Serial Number low byte
- D3 Serial Number high byte

D4

- D5 Serial Number 2 low byte
- D6 Serial Number 2 high byte

D7

D8

The IPL version number is encoded as follows:

- d6 version number bit 3
- d5 version number bit 2.
- d4 version number bit 1
- d3 version number bit 0
- d2 subversion number bit 2
- d1 subversion number bit 1
- d0 subversion number bit 0

e.g. 0x09 decodes as version 1.1.

These came from DigiPLII:

It reports PR4 with serial number 0x0788 ver 0 PR4 with serial 0x1357 ver 0 DCS240 with SN 0x0AAB ver 0.3 DCS210 with SN 0x10D4 ver 0.3

OPC_RQ_SL_DATA

Operation: Request slot data or status block.

Group: 4-Byte Message

Direction: \rightarrow Switch

Encoding:

Byte 0:

ſ	1	0	1	1	1	0	1	1	0xBB	Opcode.
---	---	---	---	---	---	---	---	---	------	---------

Byte 1:

0	n	n	n	n	n	n	n	<SLOT $#$ $>$	Slot number in the range 0x00 to
---	---	---	---	---	---	---	---	---------------	----------------------------------

0x7F. 0 returns the command sta-

tion status block

Byte 2:

Bits d2 to d0 contain the extended slot page number in the range 0x0 to 0x7. The bit d3 does something but its function is not yet known. When bit d6 is 1 then extended slot data is returned for all slots, when it is 0 standard slot data is returned for slots 0x00 to 0x7F.

Byte 3:

0	n	n	n	n	n	n	n	<CHK $>$	Checksum.
---	---	---	---	---	---	---	---	----------	-----------

Description:

Request slot data or status block.

Response:

if SLOTP = 0x00 then OPC_SL_RD_DATA, otherwise OPC_SL_RD_DATA_EXT.

1.5. OPCODES 47 Notes: None. $OPC_SL_RD_DATA$ Operation: Returns slot data. Description:

This command sends the data from one device to another peer to peer.

$\underline{\operatorname{SRC}}$	$\overline{\mathrm{DSTL}}$	$\overline{\text{DSTH}}$	Comments
0x0F	0x08	0x00	Discover devices broadcast message.
0x0F	0x10	0x00	Discover device response.

Response:

OPC_PEER_XFER_20 for discover devices.

Notes:

The discover response decoded peer transfer message encodes as follows:

```
D1 IPL Version Number
D2 Serial Number - low byte
D3 Serial Number - high byte
D4
D5 Serial Number 2 - low byte
D6 Serial Number 2 - high byte
D7
D8
```

The IPL version number is encoded as follows:

```
d6 version number bit 3
d5 version number bit 2.
d4 version number bit 1
d3 version number bit 0
d2 subversion number bit 2
d1 subversion number bit 1
d0 subversion number bit 0
```

e.g. 0x09 decodes as version 1.1.

These came from DigiPLII:

Byte 3:		
$\begin{array}{ c c c c c c c c c c c c c c c c c c c$	<chk></chk>	Checksum.
Description:		
This command unlinks slot SL1 from \pm	slot SL2.	
Response:		
Returns OPC_SL_RD_DATA or OPC_1	LONG_ACK.	
Notes:		

$OPC_WR_SL_DATA$

Operation: Write slot data.

Group: Variable-Byte Message

 $\underline{\text{Direction:}} \rightarrow \text{Command Station}$

Encoding:

Byte 0:

1 1 1 0 1 1 1 0 0xEF Opcode.

Byte 1:

0 | 1 | 1 | 1 | 1 | 1 | 0 | 0x0E | Message length (14 bytes).

Bytes 2 to 12 encode as per slot bytes 0 to 10.

Byte 13:

Description:

This command sends the slot data to the command station.

Response:

Returns OPC_LONG_ACK.

Notes:

None.

$OPC_WR_SL_DATA_EXT$

Operation: Write extended slot data.

Group: Variable-Byte Message

<u>Direction:</u> Command Station \rightarrow

Encoding:

Byte 0:

1 1 1 0 1 1 0 0xEE Opcode.

Byte 1:

Bytes 2 to 19 encode as per extended slot bytes 0 to 17.

Byte 20:

Description:

This command sends the slot data to the command station.

Response:

Returns OPC_LONG_ACK.

Notes:

None.

Chapter 2

Fast Clock

2.1 Summary

The command station provides a system fast clock and parameters are stored in slot #123 (0x7B). Use OPC_WR_SL_DATA to write new clock information, The current slot information can be read using OPC_RQ_SL_DATA. This will return an OPC_SL_RD_DATA message containing the fast clock information. This message is called the "sync". Other throttles will update to this sync. Note that all attached display devices keep a current clock calculation based on this sync read value, i.e. devices must not continuously poll the clock slot to generate time, but use this merely to restore sync and follow current rate etc. The clock slot is typically "pinged" or read every 70 to 100 seconds, by a single user, so all attached devices can synchronise any phase drifts. Upon seeing a sync read, all devices should reset their local sub-minute phase counter and invalidate the sync update ping generator.

2.2 Slot #123 Encoding

Byte 2:

0	n	n	n	n	n	n	n	<FRACL $>$	Sub-minute counter	low bits.
---	---	---	---	---	---	---	---	------------	--------------------	-----------

Byte 3:

The implementation and meaning of FRACL and FRACH depend upon the specific clock generator. These values should not be used externally. These values are reset when a valid sync message is seen.

That said, the following timing was derived for the DCS240.

Get:

maxTick = 0xBFF

$$ticks = maxTick - (0x3FFF - ((\& 0x7F) - ((\& 0x7F) <<7)))$$

seconds =
$$60.0 * ticks / (maxTick + 1)$$

Set:

temp = ticks - maxTick + 0x3FFF

$$\langle FRACL \rangle = temp \& 0x7F$$

$$\langle FRACH \rangle = (temp >> 7) \& 0x7F$$

Byte 4:

0	n	n	n	n	n	n	n	<MINS $>$	Fast clock minutes.	This is en-
									coded .	

Get:

temp =
$$((255 - \langle MINS \rangle) \& 0x7F) \mod 60$$

$$minutes = (60 - temp) \mod 60$$

Set:

$$<$$
MINS $> = (255 - (60 - minutes)) & 0x7F$

Byte 5:

	0	d6	d5	d4	d3	d2	d1	d0	<TRK $>$	Global	system track status.
--	---	----	----	----	----	----	----	----	----------	--------	----------------------

- d6 Reserved. Set to 0.
- d5 Reserved. Set to 0.
- d4 Reserved. Set to 0.
- d3 1 means the programming track is busy.
- d2 1 means this master implements the Network version 1.1 capability, 0 means the master is a DT200.
- d1 0 means the track is paused, broadcast an emergency stop.
- d0 1 means the DCC packets are on in the master, global power up.

Byte 6:

0	n	n	n	n	n	n	n	<HRS $>$	Fast clock hours.	This is encoded
---	---	---	---	---	---	---	---	----------	-------------------	-----------------

Get:

$$temp = ((256 - \langle HRS \rangle) \& 0x7F) \mod 24$$

 $hours = (24 - temp) \mod 24$

Set:

$$\langle HRS \rangle = (256 - (24 - hours)) \& 0x7F$$

Byte 7:

0	n	n	n	n	n	n	n	$\langle DAYS \rangle$	Fast clo	ck days.	Number	of 24
									hour clos	ck rolls		

Byte 8:

Byte 9:

0	n	n	n	n	n	n	n	<id1></id1>	Device ID low bits.
0	11	1 11	11	11	11	11	11	\1D1/	DOVICE ID IOW DIED.

Byte 10:

0	n	n	n	n	n	n	n	<id2></id2>	Device ID high bits.
0	11	11	11	11	11	111	11	\1D2/	Device in mgii bius.

ID1 and ID2 indicate the device that last set the clock. 0x00, 0x00 means that not set has happened. 0x7F, 0x7X are reserved for computer use.

Chapter 3

Updating Firmware

3.1 Bootloader Protocol 1

3.2 Bootloader Protocol 2

- 1. The IPL Setup message is sent twice to initiate the download.
- 2. Each block is sent,
- 3. The IPL End Operation message is sent.

A block consists of an IPL Address message following by 1 or more IPL Data messages.

3.2.1 IPL Setup

Byte 0:		
1 1 1 0 0 1 0 1	0xE5	OPC_PEER_XFER opcode.
Byte 1:

3.4 DMF File Format

The manufacturer's DMF file format is a modified form of the Intel Hexadecimal Object File Format. Character encoding is ASCII. The file consists of multiple "records" each terminated by an ASCII linefeed character (0x0A). There are four types of record and they appear in the file in the following order:

- 1. Sync records
- 2. Parameter records
- 3. Data records
- 4. End of File record

3.4.1 Sync Records

Sync records are used to identify the file as a DMF file. There are six sync records each consisting of a single ASCII # character (0x23).

Example:

#

#

ш

..

#

3.4.2 Parameter Records

PARAM MARK	PARAMETER NAME	NAME TERMINATOR	VALUE
! (0x21) < SPC > (0x20)	ASCII text	: (0x3A) < SPC > (0x20)	decimal value
2 bytes	variable bytes	2 byte	variable bytes

PARAMETER RECORD FORMAT

Parameter records start with a two byte PARAM MARK. This consists of the ASCII code for the exclamation mark (0x21) followed by the ASCII code for the space character (0x20). The PARAMETER NAME is next. The PARAMETER NAME is ASCII encoded text identifying the parameter. The PARAMETER NAME may include spaces. It is terminated by the NAME TERMINATOR which consists of the ASCII code for a colon

(0x3A) followed by the ASCII code for a space character (0x20). The last field is the VALUE field. This is a decimal numeric value encoded as ASCII text.

The following parameters have been identified and they are presented in the following order (it is not known if the order is significant):

- 1. Bootloader Version
- 2. Manufacturer Code
- 3. Product Code
- 4. Hardware Version
- 5. Software Version
- 6. Chunk Size
- 7. Delay
- 8. Options
- 9. First Address
- 10. Last Address
- 11. Prog Blk Size
- 12. Erase Blk Size
- 13. Erase Dly

Example:

- ! Bootloader Version: 2
- ! Manufacturer Code: 0
- ! Product Code: 88
- ! Hardware Version: 0
- ! Software Version: 2
- ! Chunk Size: 64
- ! Delay: 50
- ! Options: 2
- ! First Address: 24576
- ! Last Address: 73728
- ! Prog Blk Size: 256
- ! Erase Blk Size: 2048
- ! Erase Dly: 100

3.4.3 Data Records

RECORD MARK	RECLEN	LOAD OFFSET	RECTYP	DATA	CHKSUM
(:)					
1 byte	2 bytes	6 bytes	2 bytes	n bytes	2 bytes

DATA RECORD FORMAT

The data record provides a set of hexadecimal digits that represent the ASCII code for data bytes that make up a portion of a memory image.

Each data record begins with a RECORD MARK field containing the ASCII code for the colon (:) character (0x3A).

Each record has a RECLEN field which specifies the number of bytes of data which follows the RECTYP field of the record. Note that one data byte is represented by two ASCII characters. The maximum value of the RECLEN field is hexadecimal "FF" or 255. Although the maximum is 255, the manufacturer seems to prefer 64.

Each record has a LOAD OFFSET field which specifies the 24-bit starting load offset of the data bytes.

The RECTYP field for data records is "00".

Each record has a variable length DATA field, it consists of zero or more bytes encoded as pairs of hexadecimal digits.

Each record ends with a CHKSUM field that contains the ASCII hexadecimal representation of the two's complement of the 8-bit bytes that result from converting each pair of ASCII hexadecimal digits to one byte of binary, from and including the RECLEN field to and including the last byte of the DATA field. Therefore, the sum of all the ASCII pairs in a record after converting to binary, form the RECLEN field up to and including the CHKSUM field, is zero.

The contents of the individual fields within the record are:

RECORD MARK This field contains 0x3A, the encoding of the ASCII colon

(:) character.

RECLEN The field contains two ASCII hexadecimal digits that specify

the number of data bytes in the record. The maximum value

is "FF" or 0x4646 (255 decimal).

LOAD OFFSET This field contains six ASCII hexadecimal digits representing

the address at which the first byte of the data is to be placed.

Most significant digit is presented first.

RECTYP This field contains 0x3030, the hexadecimal encoding of the

ASCII characters "00", which specifies the record type to be

a data record.

DATA This field contains pairs of ASCII hexadecimal digits, one

pair for each data byte.

CHKSUM This field contains the check sum on the RECLEN, LOAD

OFFSET, RECTYP, and DATA fields.

Example:

:400060000057AAC3880FAAC388559AC38855AAC388553AC38855AAC38855AAC3884A0 0C38855AAC38855AAC3882DFCC38861B8C3882DFCC38861B8C3886D

3.4.4 End of File Record

RECORD MARK	RECLEN	LOAD OFFSET	RECTYP	CHKSUM
(:)	"00"	"000000"	"01"	"FF"
1 byte	2 bytes	6 bytes	2 bytes	2 bytes

END OF FILE RECORD FORMAT

The End of File Record specifies the end of the file.

The contents of the individual fields within the record are:

RECORD MARK This field contains 0x3A, the encoding of the ASCII colon

(:) character.

RECLEN The field contains 0x3030, the hexadecimal encoding of the

ASCII characters "00". Since this record does not contain

any DATA bytes, the length is zero.

LOAD OFFSET This field contains 303030303030H, the hexadecimal encod-

ing of the ASCII characters "000000", since this field is not

used for this record.

RECTYP This field contains 0x3031, the hexadecimal encoding of the

ASCII characters "01", which specifies the record type to be

an End of File Record.

CHKSUM This field contains the check sum on the RECLEN, LOAD

OFFSET, and RECTYP fields. Since all the fields are static, the check sum can also be calculated statically, and the value is 4646H, the hexadecimal encoding of the ASCII characters

"FF".

Example:

:000000001FF
